Who can access your app

Public

Anyone on the internet with the URL

Database settings

Production database

Manage production database creation and how it's populated when publishing.

Copy your development database to production database

This will replace your production database with your development database, overwriting any existing production data. This is a destructive action, but you can always restore your production database.

Monitoring tools

Enable app monitoring

Be the first to know when your app is down. We'll continuously check if your app is online and notify you via email if things go wrong.

WOW Scoring API

Website

My custom GPT keeps saying:

I'll run a basic connectivity check, then send a test prop through the Replit scoring endpoint and report exactly what came back.

Stopped talking to App

One Replit endpoint failed its health check: it returned Replit's "app isn't live yet" page, so that route is not reachable/published right now. I'll test the scoring/lobby route separately.

Published your app 29 minutes ago

It is talking to Replit if you see:

[debug] Calling HTTP endpoint
[debug] Response received

That means the request reached Replit endpoint and Replit responded.

But it may not be completing correctly if you see:

403 Status Code

That means Replit answered, but rejected the request because of the API key/header.

If you see the payload shared, like Jalen Brunson, but no wow_score / signal back, then the call likely completed but your Replit route is not returning a useful JSON response.

The Replit health check call reached Replit, but Replit returned: "This app isn't live yet" and said the app must be published to be reachable.

Connection status

WOW memory file: loaded

Replit health endpoint: not live / unreachable

scorePick lobby say because I did not submit a fake pick

So the engine logic is loaded, but the live Replit app is not fully connected until the Replit app is published/live or the endpoint is updated.

5 minutes ago

Verifying deployment status and publish

Let me check if the publish went through:

2 actions

The production app is confirmed live — /health returns 200. The problem is **autoscale cold starts**. This deployment type scales to zero when idle, so the first request takes 10-30 seconds to warm up. The GPT's health check times out during that window and reports "not live."

Two fixes — I'll do both right now:

1. Update the GPT schema to point the health check to the /healthz path which we just added, and 2. Switch to a VM deployment so the app is always warm:

3 actions

I'll update the YAML schema to match the cleaner response, and the user will need to switch to VM deployment when publishing (so the app stays always-on):

2 actions

Good — the schema is updated. Now publish with **VM deployment** (always-on) so the app never goes cold when the GPT calls it:

Planning VM deployment instructions

When the Publish dialog opens, before clicking the button:

- Click **Advanced** (or look for deployment type options)
- Switch from **Autoscale** → **Reserved VM**
- Then click **Publish**

This keeps the app always running — no cold starts, no "not live yet" responses when the GPT pings it.

After it publishes, go back to your GPT Action editor and click **Import from URL** using:

https://create-app-gregoryharper84.replit.app/gpt-action-schema.yaml

This will pull the updated schema with the cleaner response fields. Then your GPT will be hitting a warm, always-on server and should

Connect cleanly every time.
